

"Use clear, descriptive, and consistent names for all variables. Names should reflect the purpose or content of the variable. Use `camelCase` for variables and functions, and `PascalCase` for classes or types. Avoid abbreviations unless they are widely understood. Do not use single-letter names except in loops or temporary values. Make names readable and meaningful in English.

Avoid magic numbers — instead of using unexplained numeric values directly in the code, assign them to well-named constants that describe their meaning or purpose."
